# Aim of our project

This challenge asks you to build a classification model to predict the sentiment of COVID-19 tweets. The tweets have been pulled from Twitter and manual tagging has been done then.

# What is Sentiment Analysis?

**Sentiment analysis** (or **opinion mining**) is a natural language processing technique used to determine whether data is positive, negative or neutral.

Sentiment analysis is often performed on textual data to help businesses monitor brand and product sentiment in customer feedback, and understand customer needs.

# **Data Summary**

The following images gives basic detail about our data.

- Total Number of rows are 41156
- Data of type int64(2) and Object(4) are only present
- Location column has some null values.

- About 20.8% null values are present in location column, whereas all other columns are

clean.

Mull	Percentage

UserName	0.000000
ScreenName	0.000000
Location	20.871298
TweetAt	0.000000
OriginalTweet	0.000000
Sentiment	0.000000

<class 'pandas.core.frame.DataFrame'>

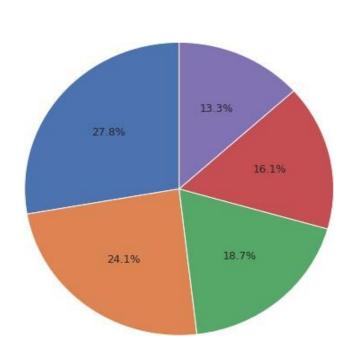

dtypes: int64(2), object(4)
memory usage: 1.9+ MB

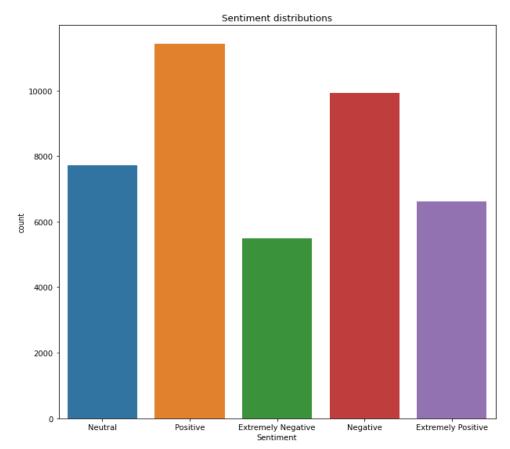

# **Exploratory Data Analysis**

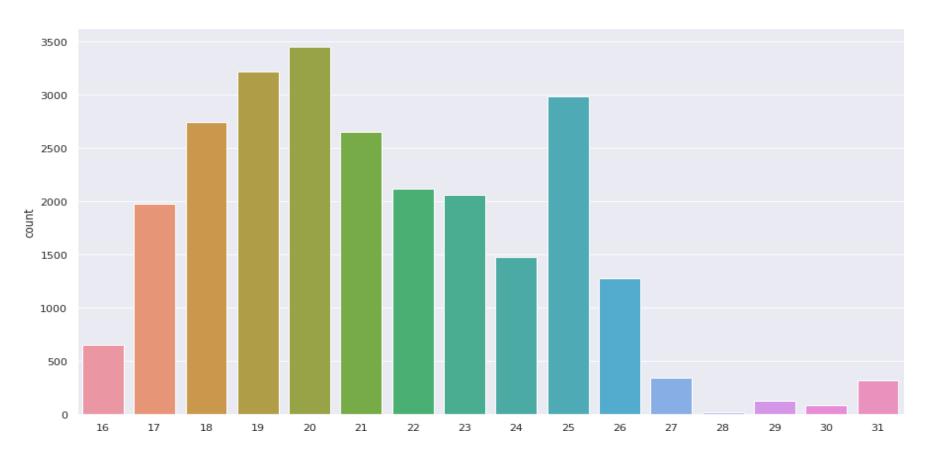

## **Sentiment Distribution**

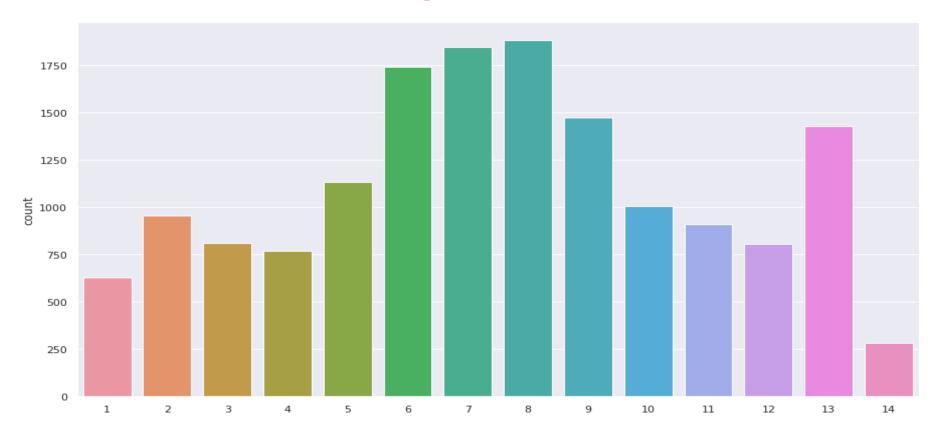

# **Tweet distribution in March**

# **Tweet distribution in April**

Top 10 locations which has most tweets from them.

	Location	Location_Count
0	London	9130
1	United States	528
2	London, England	520
3	New York, NY	395
4	Washington, DC	373
5	United Kingdom	337
6	Los Angeles, CA	281
7	India	268
8	UK	232
9	Australia	225

Top 10 dates on which maximums tweets have been made.

	OriginalTweet
TweetAt	
2020-03-20	3448
2020-03-19	3215
2020-03-25	2979
2020-03-18	2742
2020-03-21	2653
2020-03-22	2114
2020-03-23	2062
2020-03-17	1977
2020-04-08	1881
2020-04-07	1843

# **Insights from EDA**

- 1) From sentimental distribution, it was clear that 24.1% people tweets something positive, which is help-full.
- 2) There are a total of 12220 uniques locations of tweets.
- 3) London has most active people who tweets related to covid-19.
- 4) India Ranks 7th in most active locations with an average of 4.4 tweets related to corona per day.
- 5) 20 MARCH 2020 had most number of tweets related to corona, with main as lockdown in most country had started on that day.

# Preprocessing of data

The preprocessing of the text data is an essential step as it makes the raw text ready for mining, i.e., it becomes easier to extract information from the text and apply machine learning algorithms to it. If we skip this step then there is a higher chance that you are working with noisy and inconsistent data.

The objective of this step is to clean noise which is less relevant to find the sentiment of tweets such as punctuation, special characters, numbers, and terms which don't carry much weightage in context to the text.

	OriginalTweet	Sentiment	TweetMonth	Processed_text
0	@MeNyrbie @Phil_Gahan @Chrisitv https://t.co/i	Neutral	3	menyrbi philgahan chrisitv
1	advice Talk to your neighbours family to excha	Positive	3	advic talk neighbour famili exchang phone numb

# **Model Training**

# A) Count Vectorizer Method

In order to use textual data for predictive modeling, the text must be parsed to remove certain words – this process is called tokenization. These words need to then be encoded as integers, or floating-point values, for use as inputs in machine learning algorithms.

Scikit-learn's CountVectorizer is used to convert a collection of text documents to a vector of term/token counts .it also enables the preprocessing of text data prior to generating the vector representation. This functionality makes it a highly flexible feature representation module for text.

## Different models used

- 1. Logistic regression
- 2. Decision trees classifier
- 3. Multinomial naive bayes classifier

# B) Tf-IDF Method

This is another method which is based on the frequency method but it is different to the bag-of- words approach in the sense that it takes into account, not just the occurrence of a word in a single document (or tweet) but in the entire corpus.

TF-IDF works by penalizing the common words by assigning them lower weights while giving importance to words which are rare in the entire corpus but appear in good numbers in few documents.

Let's have a look at the important terms related to TF-IDF:

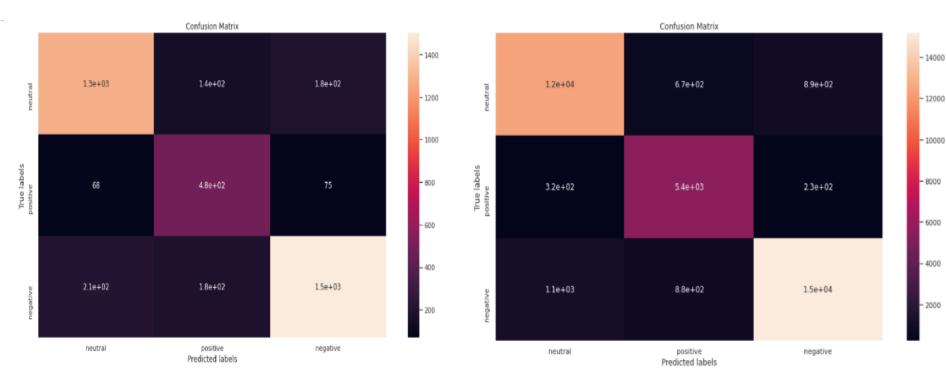

- TF = (Number of times term t appears in a document)/(Number of terms in the document)
- IDF = log(N/n), where, N is the total number of documents and n is the number of documents the term t has appeared in.
- TF-IDF = TF\*IDF

# Conclusion

We are finally at the conclusion of our project!

Coming from the beginning we did EDA on the dataset and also cleaned the data according to our needs. After that we were able to draw relevant conclusions from the given data and then we trained our model on logistic regression.

For our model we were able to get the accuracy of 88% for the train set and accuracy of 80% for the test set using logistic regression.

Given the size of data and the amount of irrelevance in the data, the above score is good.
